Dedication

This book is tribute to my parents (Adina & Claude Parchment). Thank you both for everything.

Table of Contents

Dedication	4
Table of Contents	5
Introduction.....	6
Preface	6
Acknowledgments	6
Chapter 1 - Introduction to Python.....	7
Chapter 2 - Variables and Data Types.....	8
Chapter 3 - Comparison Operators.....	10
Chapter 4 - User Input and Output.....	12
Chapter 5 - Conditional Statements	15
Chapter 6 - Lists.....	18
Chapter 7 - Loops.....	20
Chapter 8 - Dictionaries.....	22
Chapter 9 - Functions.....	24
Chapter 10 - Classes	26
About the Author	28

Introduction

Welcome to **“Learn Smarter - Python 1st edition”** a technical beginner's guide to learning one of the most popular programming languages in the world. In this book, you'll embark on a journey to understand the fundamental concepts of Python programming and how to apply them in real-world scenarios. Within “Learn Smarter” every chapter covered you’ll encounter a challenge to catapult your programming skills to the next level.

Preface

This book is designed for absolute beginners with no prior programming experience. Whether you're a student, a professional looking to switch careers, or simply curious about coding, this book will provide you with a solid foundation in Python programming.

In writing this book, my goal is to provide entry and junior level coders a with a practical and technical guide for developing their coding skills.

Acknowledgments

I would like to express my sincere gratitude to my parents for their support and encouragement throughout the writing of this book.

Chapter 1 - Introduction to Python

Welcome to Python programming! Python is a versatile, easy-to-learn language used in web development, data analysis, AI, and more. It's known for its readability and simplicity.

- **Who created Python?**

Python was created by **Guido van Rossum**, a Dutch programmer, and it was first released in 1991.

- **Why learn Python?**

Python is versatile, readable, boasts a large community, and is in high demand in the job market.

- **How to set up Python?**

We'll install python from **python.org**, however for the first few chapters we'll use an embedded code editor.

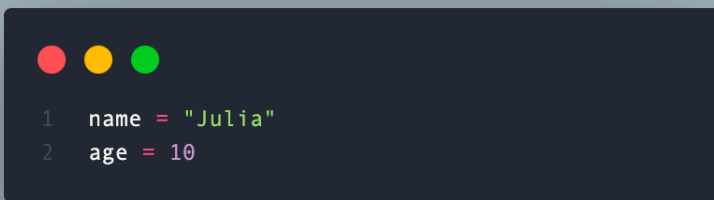

Chapter 1 - Introduction to Python Challenge

Chapter 2 - Variables and Data Types

We'll learn about variables and basic data types. Imagine variables like boxes where you can put stuff, and data types like the different kinds of information you can put in those boxes.

- **What are Variables and Data Types?**

Variables are like labeled containers. Within these containers we place our information to be used for later use. The information placed in these containers can be numbers, words, and lists of things, just like how you might have separate boxes for your shoes, clothes, and books. Each container holds a specific type of information, making it easier for the computer to understand what we're working with.

A terminal window with a dark background and three colored window control buttons (red, yellow, green) in the top left corner. It displays two lines of code: line 1 is 'name = "Julia"' and line 2 is 'age = 10'.

```
1 name = "Julia"
2 age = 10
```

variable = information

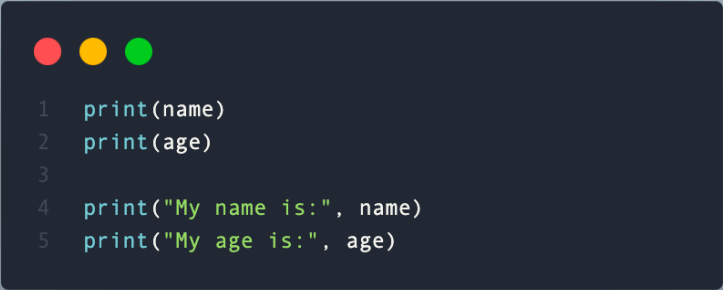

The image above displays two variables. A variable called name with the information of someone named Julia, and a variable called age with someone's age as 10.

- **What are strings and integers?**

Did you Notice “Julia” is in quotes and our number / integer is not? That’s because strings are represented as quotes. Think of strings like colored beads placed on a string necklace. Each bead represents a letter or a symbol, while integers are plain number blocks used for counting and math.

- **What is print: `print()`**

Suppose we want to see what’s stored in our variables. We can use a special Python key word called **print**.

```
1 print(name)
2 print(age)
3
4 print("My name is:", name)
5 print("My age is:", age)
```

Chapter 2 - Variables and Data Types Challenge

Chapter 3 - Comparison Operators

Suppose you have two numbers or pieces of information, like apples and oranges. Comparison operators in Python are like tools you can use to compare these numbers or pieces of information to see how they relate to each other. Here are some of the main comparison operators:

- **Equal to: ==**

Checks if two things are exactly the same.

```
1 print(2 == 2) # True
2 print(2 == "2") # False
3 print("4" == "four") # False
4 print("3" == '3') # True
5 print("python" == "python") # True
6 print("Python" == "python") # False
```

- **Not equal to: !=**

Checks if two things are not the same.

- **Greater than: >**

Checks if one thing is bigger than another.

- **Less than: <**

Checks if one thing is smaller than another.

- **Greater than or equal to: >=**

Checks if one thing is either bigger than or equal to another.

- **Less than or equal to: <=**

Checks if one thing is either smaller than or equal to another.

```
1 print(5 != 3) # True
2 print(7 > 12) # False
3 print(2 < 6) # True
4 print(3 >= 3) # True
5 print(4 <= 3) # False
```

- **Bonus:**

In addition to comparison operators, Python features logical operators: **and**, **or**, and **not**. Alongside these logical operators, Python also has **True** and **False** values.

Chapter 3 - Comparison Operators Challenge

Chapter 4 - User Input and Output

Imagine you're playing a game on your computer, and the game wants to ask you something, like your name or age. Python's **input()** is like a way for the game to talk to you and ask for information. So, when the game asks, "What's your name?" and you type "Jane" and hit Enter, Python's input helps the game understand what you typed. It's like having a conversation with the computer!

- **What if the users input is a integer: **int()****

Let's say the question is "What's your lucky number?" and you answer "15". Even-though it appears to be an integer the input method converts everything to a string. To transform a stringed integer to a whole number use the **int** method as followed.

```
1 lucky_number = int(input("What's your lucky number? "))
```

- **What if the users input is a float: **float()****

Now, imagine the question is "How much does a slice of pizza cost?" and you answer "2.75", that's also a string. We would have to use the **float** method to convert our answer if we want to probably use it in a math equation.

```
1 pizza_cost = float(input("How much does a slice of pizza cost? "))
```

- **What if the users input is a string: `str()`**

Finally, if the question is "What's your favorite color?" and you answer "blue", no converting is needed.

However if you feel the need to convert a int or a float into a string

```
1 favorite_color = input("What's your favorite color? ")
```

- **f-string:**

An f-string is like a magical way to put your age or any other information into a sentence easily. You just put an 'f' before the string of text you want to write, and then inside the text, you can put curly braces {} where you want to put your information.

```
1 age = 10
2 print(f"I am {age} years old.")
```

- **Bonus:**

When creating a variable with more than one word use snake_case, an underscore after every word. When we have an input as a stringed int / float we can convert the input to a int or float.

Chapter 4 - User Input and Output Challenge

Chapter 5 - Conditional Statements

Just like choosing between paths in a game, we sometimes need to make decisions in our code based on certain conditions.

- **The `if` Statement:**

It's like asking a question. If a condition is true, it does something.

```
1 age = int(input("What's your age? "))
2
3 if age > 10:
4     print("You are growing up!")
```

- **The `elif` Statement:**

When we have more than one condition, we use "elif" (short for "else if").

```
1 age = int(input("What's your age? "))
2
3 if age == 10:
4     print("You're 10, me too!")
5 elif age < 10:
6     print("You're very young.")
```

- **The `else` Statement:**

The final result when your if and or elif don't pass as true.

```
1 age = int(input("What's your age? "))
2
3 if age == 10:
4     print("You're 10, me too!")
5 elif age < 10:
6     print("You're very young.")
7 else:
8     print("You're older than me")
9
```

- **Bonus:**

You can have multiple single if or elif statements however you can only have one else in a single block of code.

Chapter 5 - Conditional Statement Challenge

Chapter 6 - Lists

We learned about variables and how they can contain a string, integer, and a boolean but we also have a list.

- **List:**

Although a variable can technically hold only one item at a time, a list is capable of containing a plethora of items with diverse data types. The distinction lies in its presentation: lists are denoted by square brackets enclosing multiple items separated by commas.

```
1  foods = ["avocado", "bagels", "pistachios", "bananas"]
2  print(foods)
3
4  items = ["pencils", 4, "pens", 8, "books", True]
5  print(items)
```

- **Indexing:**

Suppose we want to find a specific item within our list, we can easily access it by indexing it numeric position. We start from 0, 1, 2... and so on.

```
1  foods = ["avocado", "bagels", "pistachios", "bananas"]
2  print(foods[0])
3
4  items = ["pencils", 4, "pens", 8, "books", True]
5  print(items[3])
```

- **Bonus:**

You can have multiple single if or elif statements however you can only have one else in a single block of code.

Chapter 6 - Lists Challenge

Chapter 7 - Loops

Think of a loop as an assistant that handles a repetitive task for you. We simply type **for** iterator_name **in** the_list_name to loop thru.

- **for loop:**

Imagine we're at a grocery store with a shopping cart full of items. When we go to checkout, each item gets scanned and added to our bill. This is similar to how a for loop works. In a for loop, we go through a group of items (like numbers or words) one by one. It's like scanning each item at the checkout. Just as we see the item number or name on our bill, during the loop, we can see each item's value or name as we go through them one by one.

```
1  foods = ["avocado", "bagels", "pistachios", "bananas"]
2
3  for food in foods:
4      print(food)
```

- **Bonus:**

In addition to a for loop, there's also a while loop, which loops for a given duration until a requirement is met.

```
1 friends = 0
2
3 while friends <= 5:
4     print('I have', friends, 'friends')
5     friends += 1
```

Chapter 7 - Loops Challenge

Chapter 8 - Dictionaries

A dictionary in Python is like a book that stores information in pairs. Imagine you have a book where you can find information by looking at the special labels. Each label tells you exactly where to find something in the book.

- **Dict: {}**

Dictionaries are like special containers where you have keys on the left and their matching values on the right, separated by a colon. These pairs are called key-value pairs. Values can be numbers (like ints or floats), words (strings), lists, other dictionaries, and even more! Please take notice of the curly brackets / braces and colon.

```
1  group = {
2      "first_name": "Tommy",
3      "last_name": "Tutone",
4      "age": None,
5      "top_song": [867, 5309, "Jenny-Jenny"]
6  }
7
8  artist = {
9      "first_name": "Rick",
10     "last_name": "Astley",
11     "age": 58,
12     "top_song": {
13         1: "Never Gonna Give You Up",
14     }
15 }
```

- **Bonus:**

You can have multiple single if or elif statements however you can only have one else in a single block of code.

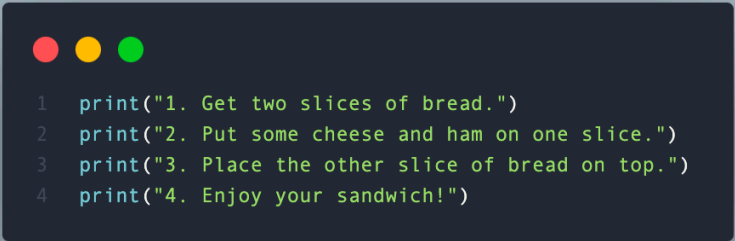

Chapter 8 - Dictionaries Challenge

Chapter 9 - Functions

Think of a function like a recipe in a cookbook. It's a set of instructions that tells the computer how to do something. Let's say you want to make a sandwich. The recipe would tell you what ingredients you need and the steps to follow to make the sandwich.

- **Functions: `def`**

In Python, a function works similarly. It's a block of code that you can use over and over again to perform a specific task. Within our function notice the key word `return`. This word calls or invokes our function to run through the repetitive statements when want to return our information. Please take notice to create a function we use the `def` keyword and parentheses after the function name.

```
1 print("1. Get two slices of bread.")
2 print("2. Put some cheese and ham on one slice.")
3 print("3. Place the other slice of bread on top.")
4 print("4. Enjoy your sandwich!")
```

If we wanted to repeat our sandwich making process we would have to copy and paste our four lines of code.

```
1 def make_sandwich():
2     return(
3         "1. Get two slices of bread.",
4         "2. Put some cheese and ham on one slice.",
5         "3. Place the other slice of bread on top.",
6         "4. Enjoy your sandwich!")
7
8 print(make_sandwich())
```

With our function on the other hand if we want to showcase or sandwich making process we can just copy paste `print(make_sandwich())` a second time. Simple!

Chapter 9 - Functions Challenge

Chapter 10 - Classes

Imagine you're customizing a character in a video game. The default character presented to you is a blueprint so to say. This blueprint is the starting point from which you create, customize or spawn new characters from. Each character you create has its own special properties or abilities, like hair color or special move. Now, think of classes in Python as blueprints for creating these different types of characters.

- **class:**

In Python, a class uses the class key word, followed by the name of our class in Pascal Case, for example:

LikeThisClassName. We initialize or construct our class to have a `def __init__(self)`. This allows properties in our class, similar to nouns. Next we can create a method which acts as verbs or functions which typically modify our attributes.

```
1  class Human:
2      def __init__(self, name, age, gender, adjective):
3          self.name = name
4          self.age = age
5          self.gender = gender
6          self.adjective = adjective
7
8      def describe(self):
9          return [
10             f"My name is {self.name}",
11             f"I'm {self.age} years old",
12             f"{self.adjective}, and I'm {self.gender}."]
13
14  alice = Human("Alice", 10, "female", "brave")
15  print(alice.describe())
```

Chapter 10 - Classes Challenge
